

# Gippsland Lakes Blue-green algae update

December 7 2011

Factsheet No 2

## What is the current situation?

A blue-green algal bloom of the species *Nodularia spumigena* is currently affecting some parts of the Gippsland Lakes, including Paynesville Marina, Chinamans Creek, Eagle Point, Boxes Creek, Nungurner jetty, some areas of Lake King, Bancroft Bay, Metung wharf, Shaving Point, Lake King jetty, Cunninghame Arm and lower North Arm.

Latest testing has shown that blue-green algae levels in McMillans Strait, between Raymond Island and the mainland are now above the trigger levels for the installation of warning signs.

Concentrations of *Nodularia spumigena* found in the listed locations currently exceed the health trigger value for recreational activities as specified in the Guidelines for Managing Risks in Recreational Water<sup>1</sup>. Exposure to *Nodularia spumigena* through direct contact and ingestion at these levels can result in adverse health effects.

Algal blooms are not unusual on the Lakes and can be a common sight as temperatures warm up and conditions become suitable for blooms.

Recent monitoring has shown that the following areas do **not** currently appear to be affected by high levels of blue-green algae:

Newlands Arm and Duck Arm, west of Paynesville, and areas west of and including Wattle Point.

## How might the Algae in Gippsland Lakes affect me?

The algae have been detected at levels that may have health implications for humans, domestic animals and livestock.

The Department of Health advises that contact with the water should be avoided, particularly in areas where scums and discoloured water are evident.

## Can I swim and undertake other watersports?

Swimming and any water sport or activity, including skiing and inflatable tubes and 'donuts' that result in direct contact with affected water are not recommended.

## What should I do if I come into contact with affected water?

If contact is made, users should remove any affected clothing and wash themselves thoroughly with clean water after coming ashore. Wetsuits should be thoroughly rinsed before being worn again to remove any traces of algae.

Users who experience any health effects following recreational use of the Lakes should seek medical advice. For further information on health issues contact Department of Health's Environmental Health Unit on 1300 761 874.

## Can my dog swim in the Gippsland Lakes?

Dogs and other pets can also be affected, so it is safer not to let them enter the water in areas where there are warning signs in place or discoloured water is evident.

## What is being done?

The Department of Sustainability and Environment (DSE) is working with a multi-agency Incident Management Team to monitor the situation. Signs will be erected at key sites around the Lakes to advise the public not to come into contact with affected water.

## How long will the bloom last?

Tests are being conducted on a regular basis to monitor the type, amount and extent of algae present. There is no definite length of time that the bloom will remain. Once the testing shows the bloom has cleared the message will be relayed to the public.

## What other places can I visit in Gippsland?

There are plenty of beautiful places around the Gippsland Lakes for people to visit and enjoy the outdoors. Boating can still be enjoyed in many areas of the lakes, swimming at patrolled beaches and fishing on Ninety Mile beach is encouraged and fantastic walking and cycling trails are accessible throughout the lakes area.

Contact local Visitor Information Centres at Bairnsdale on 0351 523444 or Lakes Entrance on 0351 552966 or visit [www.inspiredbygippsland.com.au](http://www.inspiredbygippsland.com.au) for information about areas to visit and activities to pursue in Gippsland.

## General information about Blue-green algae

- Blue-green algae (cyanobacteria) are bacterial organisms that undergo photosynthesis, and have some of the characteristics of bacteria and of algae. They can appear singularly or in colonies, and are present in almost all aquatic ecosystems, including creeks, rivers, lakes and wetlands. Individual cells are very small, so blue-green algae can be present in a water-body without being visible.
- Under certain environmental conditions, numbers can increase rapidly and blooms, or scums, become easily visible across the water surface. The blooms range in colour from dark-green to yellowish brown.
- Blue-green algae rely on sunlight for energy, with their growth rate determined by the level of nutrients available in the water. Unlike other algae they also contain pockets of gas called "vacuoles" which allow them to control their buoyancy. This ability to move within the water column gives blue-green algae an advantage over other organisms in competing for nutrients. However, as soon as the water becomes turbulent, they cannot remain afloat, and this lessens their advantage and so reduces the growth rate.
- Waters that flow slowly with low turbulence are at a particularly high risk of algal blooms. Blooms are likely to form when the water is relatively still, nutrient levels are high and

## Gippsland Lakes Blue-green algae update

temperatures are warm. When conditions remain favourable, blooms can last weeks to months especially if nutrient levels are high. Cooler, windy weather or increased flow may reduce or stop them fairly quickly.

- When blooms die, the decomposition of the algal cells consumes the oxygen in the water. Breakdown of large blooms can deplete water oxygen levels to the point where fish suffocate. Fish that are dead, dying or swimming erratically should not be handled or consumed. You can report a fish death event to the EPA on (03) 9695 2777.
- Blue-green algal blooms typically occur during the summer/autumn period. They have been recorded in the Gippsland Lakes in 1965, 1971, 1974, 1987-88, 1995-96, 1996-97, 1999, 2001, 2002 and 2008/9.
